Negation on the Australian Plan

Francesco Berto^{1,2} • Greg Restall³

Received: 25 November 2017 / Accepted: 30 March 2019 / Published online: 22 April 2019 © The Author(s) 2019

Abstract

We present and defend the Australian Plan semantics for negation. This is a comprehensive account, suitable for a variety of different logics. It is based on two ideas. The first is that negation is an exclusion-expressing device: we utter negations to express incompatibilities. The second is that, because incompatibility is modal, negation is a modal operator as well. It can, then, be modelled as a quantifier over points in frames, restricted by accessibility relations representing compatibilities and incompatibilities between such points. We defuse a number of objections to this Plan, raised by supporters of the American Plan for negation, in which negation is handled via a many-valued semantics. We show that the Australian Plan has substantial advantages over the American Plan.

- 2. TRUTH CONDITIONS FOR NEGATION
- 3. TAKING THO DIFFERENT PERSPECTIVES
- 4. CARD SELECTION TASKS
- J. WHERE TO CO FROM HERE

7 A is true if and only if A is not true.

In terms of Situations

SILTA if and only if SIHA

In terms of truth values

$$v(\neg A)=1$$
 if and only if $v(A)\neq 1$

$$v(\neg A)=1$$
 if and only if $v(A)=0$

$$v(\neg A)=0$$
 if and only if $v(A)=1$

$$V(\neg A)=1$$
 if and only if $V(A)=0$
 $V(\neg A)=i$ if and only if $V(A)=i$
 $V(\neg A)=0$ if and only if $V(A)=1$

If the untermediate velue is taken to be neither true nor false, we have a touth-value gap.

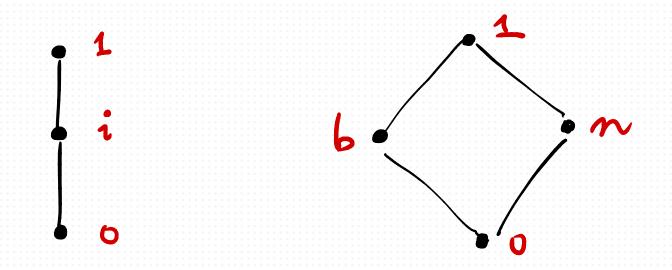

$$V(\neg A)=1$$
 if and only if $V(A)=0$
 $V(\neg A)=i$ if and only if $V(A)=i$
 $V(\neg A)=0$ if and only if $V(A)=1$

If the intermediate velue is taken to be both true and false, we have a touth-value glut.

$$N(\neg A)=1$$
 if and only if $N(A)=0$
 $N(\neg A)=M$ if and only if $N(A)=M$
 $N(\neg A)=b$ if and only if $N(A)=b$
 $N(\neg A)=0$ if and only if $N(A)=1$

If you really want, you can have two intomediate values for 'both' and 'neither' - gluts & gaps.

(If you wonder how to evaluate the other legrent operators in schemes When this, meditate on these Hasse diagrams. Conjunction is greatest lover bound, dispurction, least upper bound, as usual.)

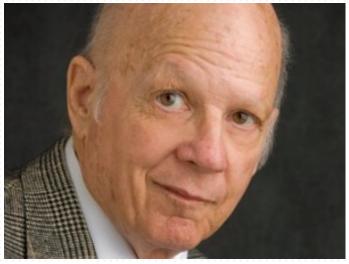

In the relevant logic tradition, this scheme for negation (generalising beyond two truth values) is called the AMERICAN PLAN, because it comes from the work of the two American logicions

There is More to Negation than Modality

Michael De¹ · Hitoshi Omori²

Received: 17 February 2016 / Accepted: 20 January 2017 © Springer Science+Business Media Dordrecht 2017

Abstract There is a relatively recent trend in treating negation as a modal operator. One such reason is that doing so provides a uniform semantics for the negations of a wide variety of logics and arguably speaks to a longstanding challenge of Quine put to non-classical logics. One might be tempted to draw the conclusion that negation is a modal operator, a claim Francesco Berto (Mind, 124(495), 761-793, 2015) defends at length in a recent paper. According to one such modal account, the negation of a sentence is true at a world x just in case all the worlds at which the sentence is true are incompatible with x. Incompatibility is taken to be the key notion in the account, and what minimal properties a negation has comes down to which minimal conditions incompatibility satisfies. Our aims in this paper are twofold. First, we wish to point out problems for the modal account that make us question its tenability on a fundamental level. Second, in its place we propose an alternative, non-modal, account of negation as a contradictory-forming operator that we argue is superior to, and more natural than, the modal account.

My task here is not to ajudicate this dispute, but to explore one of the ways the distinctive features of the Australian Plan Semantics can be applied.

Before that, let's see another tradition in the Semantics of negation: NECATION AS FAILURE, from legic programming of database theory

NEGATION AS FAILURE

Keith L. Clark

Department of Computer Science & Statistics
Queen Mary College, London, England

ABSTRACT

A query evaluation process for a logic data base comprising a set of clauses is described. It is essentially a Horn clause theorem prover augmented with a special inference rule for dealing with negation. This is the negation as failure inference rule whereby ~ P can be inferred if every possible proof of P fails. The chief advantage of the query evaluator described is the effeciency with which it can be implemented. Moreover, we show that the negation as failure rule only allows us to conclude negated facts that could be inferred from the axioms of the completed data base, a data base of relation definitions and equality schemas that we consider is implicitly given by the data base of clauses. We also show that when the clause data base and the queries satisfy certain con-

Treat a doctabase Das verifying TA if and only of D fails to verify A.

(This looks a lot like Boolean Negation, but this is a database, not a world.) Which of these approaches is CORRECT?

I am not the person to give you a direct answer to that kind of question.

REASONING ABOUT A RULE

BY

P. C. WASON

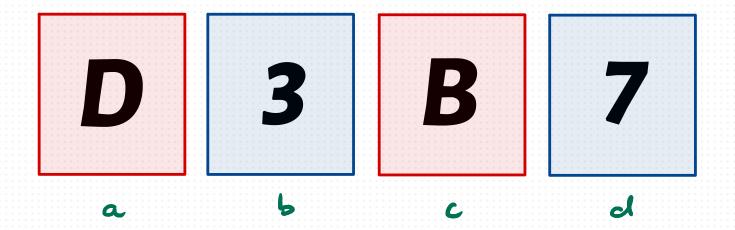

From Psycholinguistics Research Unit, University College London

Two experiments were carried out to investigate the difficulty of making the contrapositive inference from conditional sentences of the form, "if P then Q." This inference, that not-P follows from not-Q, requires the transformation of the information presented in the conditional sentence. It is suggested that the difficulty is due to a mental set for expecting a relation of truth, correspondence, or match to hold between sentences and states of affairs. The elicitation of the inference was not facilitated by attempting to induce two kinds of therapy designed to break this set. It is argued that the subjects did not give evidence of having acquired the characteristics of Piaget's "formal operational thought."

Perhaps surprisingly, performance is much better if you negate the consequent: "If a cord has a D on one side there isn't a 3 on the other." (Choose a 4 b.)

MATCHING BIAS IN THE SELECTION TASK

By J. ST B. T. EVANS AND J. S. LYNCH Psychology Section, City of London Polytechnic

A previous study (Evans, 1972) found that subjects tend to match rather than alter named values when constructing verifying and falsifying cases of conditional rules. It was suggested that this tendency ('matching bias') might account for the responses normally observed in Wason's (1968, 1969) 'selection task'. This suggestion was tested by giving subjects the selection task with conditional rules in which the presence and absence of negative components was systematically varied, to see whether subjects consistently attempted to verify the rules (Wason's theory) or whether they continued to choose the matching values despite the presence of negatives, which would reverse the logical meaning of such selections. Significant matching tendencies were observed on four independent measures, and the overall pattern, with matching bias cancelled out, gave no evidence for a verification bias, indicating instead that the logically correct values were most frequently chosen.

Wason & Johnson-Laird (1972) review a number of recent studies about the reasoning patterns generally obtained in Wason's 'selection task'. That task was

There is a vast literature on cord selection tasks.

It is not our aim to get to the bottom of all of it.

We want to see how contemporary work in the semantics of negation can be tested for cognitive significance. Insight 1: Reasoning accurately about negations (and falsity) involves generalising over compatible evidence bases, and this is complicated. It is not surprising that we find this difficult.

Pusight 2: If System 1 judgements about negations over quick-and-dirty negation as foulure judgements, it's not susprising that we overgenerate answers.

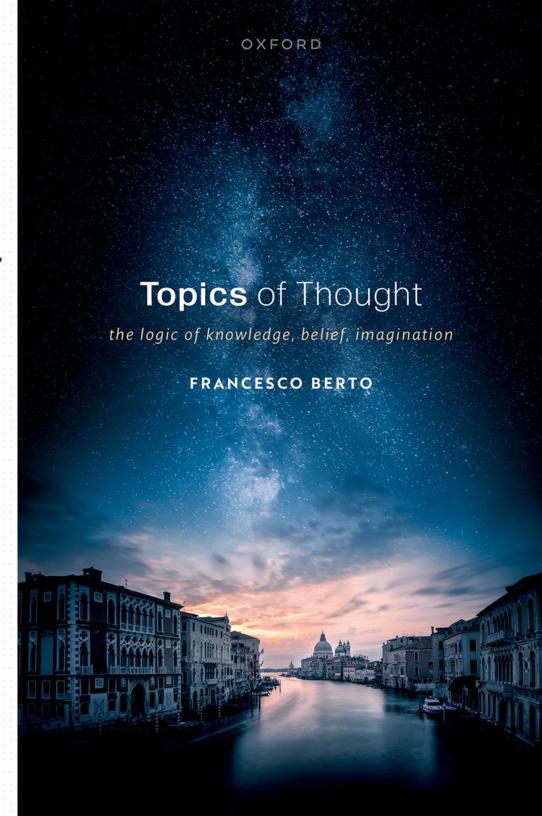

How can we account for greater success in the pegated consequent form of the task:

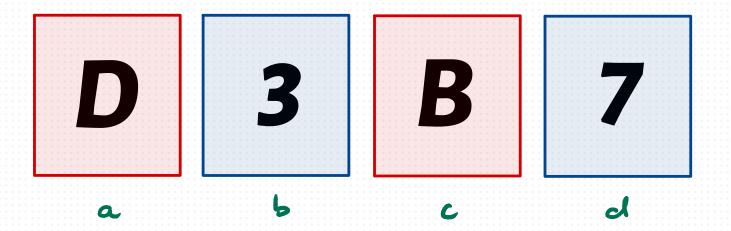

"If there is a D on one side of the cord there isn't a 3 on the other"?

Here we might use some cancepts from Berti's 2022 book Topics of Thought.

Indgements do not only have truth conditions - they also have topics.

Negation is topic-transporent. $t(\neg A) = t(A)$. So is the material conditional. $t(A \rightarrow B) = t(A) \oplus t(B)$.

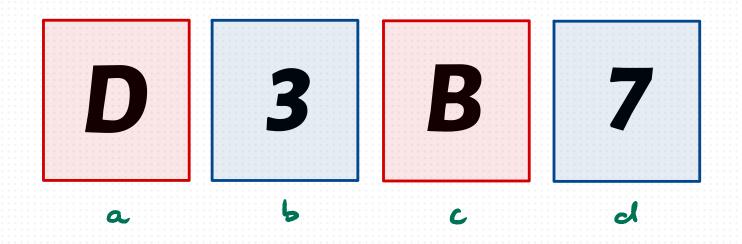

"If there is a D on one side of the cord there isn't a 3 on the other"?

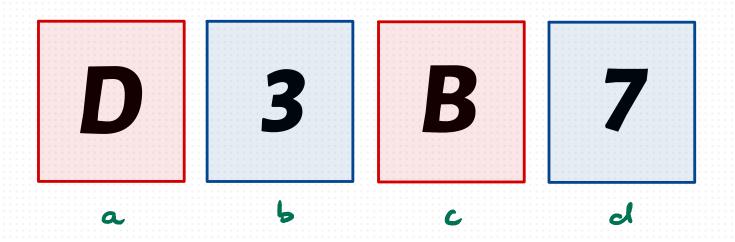

$$t(Dn \rightarrow 73n) = t(Dn) \oplus t(3n)$$

$$t(Dn \rightarrow 3n) = t(Dn) \oplus t(3n)$$

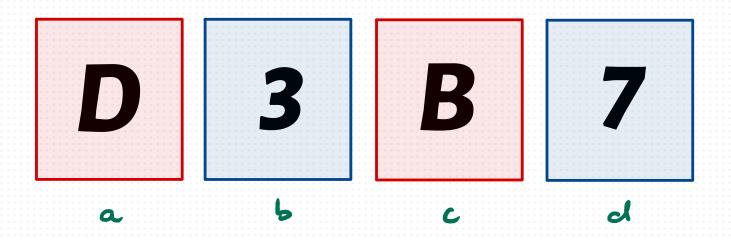

"If there is a D on one side of the cord there isn'? ?

is guided by topic (in this sence) then it is not suprising that we might pick a & b (at least) in this scenario, whether we check $D_{x\to 73z}$ or $D_x\to 3z$, Since being a D & being a 3 is clearly on topic.

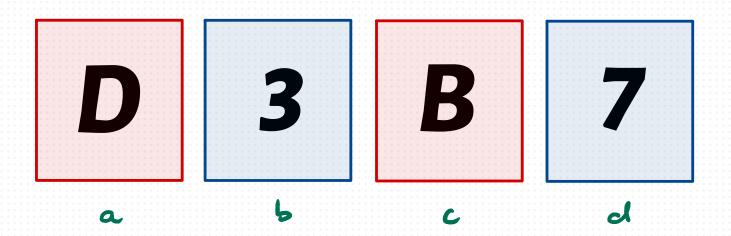

"If there is a D on one side of the cord there isn'? ?

If we stop there, to consider only the clearly D and 3 cords, without considering the other sides of c & d, we chance on the right answer of the Dx -> 732 task, but err on the Dz -> 32 task.

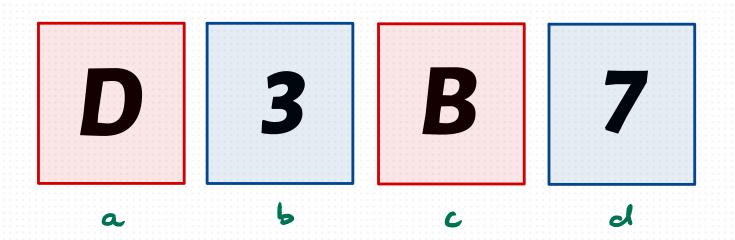

"If there is a D on one side of the cord there isn't a 3 on the other"?

Combining topic sensitivity with regation as failure (System 1) judgements brings every cord into salience, which could explain My peopleme prome to overgenerate answers in either case,

Contemporary work in the philosophy of lagic can give us new ideas about possible cagnitive mechanisms at play in our reasoning judgements, whether fast or Slow.

Contemporary work in the philosophy of lagic can give us new ideas about possible cagnitive mechanisms at play in our reasoning judgements, whether fast or Slow.

There does not need to be a one-size-fits-all approach. Pluralism seems fitting here!
